

Rainforest Foundation
Norway

An aerial photograph of a dense tropical rainforest at sunset. The sun is low on the horizon, casting a warm, golden glow over the canopy. The forest stretches across the frame, with layers of trees creating a textured pattern. The sky above is a mix of orange, yellow, and blue, with wispy clouds. The overall atmosphere is serene and highlights the beauty of the natural environment.

State of the tropical rainforest

Introduction

This report is the first in the world of its kind. Granted, there has been scattered research on the state and extension of the tropical rainforest. However, that research has often applied varying methodologies and they are not always comparable, nor do they necessarily present the latest data or use the same reference year. This has made it impossible to monitor the global state and historical development of the tropical rainforest in an easy and reliable manner.

Why is this important? Simply put because the tropical rainforest is arguably the most important terrestrial ecosystem on the planet.

It provides a wide range of invaluable ecosystem services for all life on Earth. Yet available data on the state of this particular tropical forest type has been surprisingly inadequate. Along with a scarcity of global biome specific forest data, misconceptions about tropical rainforests flourish. This confuses the public discourse on tropical rainforest, and at worst it could mislead policy makers and policy influencers about the true state of this unique ecosystem.

The world cannot afford that. We need the debate over how to save the rest of the tropical rainforests to be founded on reliable data on the condition of these forests. “One third” is a key takeaway from this report:

- One third of the original tropical rainforest is gone.
- One third of the original tropical rainforest is degraded.
- One third of the original tropical rainforest is still intact.

There are both positive and alarming angles to take from these simple facts. It’s positive that we have not cleared half of the world’s tropical rainforest, a common statement found on various credible web sites. It’s alarming that only one third is left intact given that degraded forests often struggle to sustain themselves.

This report is the first complete overview of the state of the world’s tropical rainforest at present and in a historical perspective. It aims to fill a critical knowledge gap in the effort to preserve these invaluable forests for future generations.

The tropical rainforest

Photo: Thomas Marent

The tropical rainforest is a unique ecosystem in particularly three significant ways:

- It covers only 6,5 % of the Earth's terrestrial surface, yet holds more than half of the world's biological diversity.² No other ecosystem on Earth can match the biological diversity of this forest.
- It stores more carbon in live biomass than any other ecosystem on the planet.³ Thus, stopping the deforestation and degradation of tropical rainforests is key to be

able to slow the human caused warming of Earth's oceans and atmosphere.

- It cools the air and creates evaporation more effectively than open water. It creates what has been termed the "biotic pump", which secures rainfall thousands of kilometres inland from the oceans⁴. It affects precipitation patterns all over the world⁵.

Defining tropical rainforests

Precipitation

There is no straightforward definition of a tropical rainforest. In terms of precipitation, some can receive more than 9 meters of rainfall annually, with little seasonal differences, like the Choco-Darien rainforest along the northern Pacific coast of South America⁶. The forests in the tropics that receive more than 2,5 meters of rainfall per year with little seasonal variations are growing in a climate

that deterministically supports rainforests. This means that the climate is the main driving force of the kind of ecosystem that develops. In such a climatological climax for a tropical rainforest, no other ecosystem will naturally grow⁷. This kind of rainforest climate is mainly found in interior parts of the Amazon and in Southeast Asia.

Other tropical rainforests can receive as little as 1,5 meters of rainfall a year, with a dry season that can last 3-5 months. The drier months are not rain free, but they receive significantly less rainfall than other months. These are tropical semi-evergreen rainforests, where some trees can shed the leaves during a short period of the dry season to conserve energy. This is a climate zone that also supports savannas. In this climate zone, the establishment of fire prone grasses strongly determines the establishment of a forest or savanna environment. Light-dependant fire prone grasses sustain the regular fires of the savannas. In contrast to savannas, rainforests do not consist of fire adapted plants and trees. Due to the lack of sufficient sunlight, the closed canopy of a rainforest does not allow for fire prone grasses to grow⁸. The forest also holds moisture well, so when the fires of the savannas reach the edge of intact rainforests, they die out.

This can create sharp borders between rainforest and savanna, with no transitional ecosystem between them. These are called forest-savanna mosaics and cover large areas of especially Amazonia and equatorial Africa⁹. Almost the entire Central African rainforest grows in this climate zone. The Yucatan rainforest in Mexico, Guatemala and Belize, and much of mainland Asia's rainforest also grow in this forest-savanna climate¹⁰. Over thousands of years, there is a slow back and forth struggle between forests and savannas in these areas, driven by many different factors¹¹, though large blocks of rainforests have remained relatively stable over time. Today, humans degrade enormous rainforest areas each year

◀◀ This wet and frost-free climate allows plants to continually grow throughout the year without periods of energy conservation due to frost or drought. ▶▶

so that the tropical rainforests become drier and lose the ability to withstand fires¹². If conditions change significantly, the forest ecosystem can collapse and transition to savanna. Thousands of kilometres of degraded rainforest burn every year due to human caused forest degradation, and human induced fires¹³.

In some areas, the soil and climatological conditions create transitional forests between rainforests and dry savannas. These are called everything from tropical dry forests or tropical monsoon forests, to seasonal tropical forests and tropical moist deciduous forests. This forest type has a prolonged and distinct dry season during which many of the trees shed their leaves¹⁴. They tend to flank the rainforest to the north or south. Even though many of these transitional forests can have a dense canopy much of the year and consist of broad-leaved trees, due to the drier climate and prolonged dry season, the trees have a lower stature than those of the rainforest. These forests also consist of fewer plant and animal species, and they store less carbon in live biomass¹⁵.

They can, however, have high endemic species composition. These forests can consist of a certain amount of fire adapted tree species, making them more adapted to fires than a rainforest environment¹⁶. However, this fire adaptability varies, even within the same forest area, and none can withstand fires of high intensity and durability¹⁷. Not all tropical dry or monsoon forests are transitional forests. The largest tropical dry forest in the world, which also is a transitional forest, is the Chiquitano forest in Bolivia and Brazil¹⁸.

Temperature

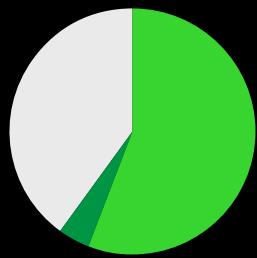

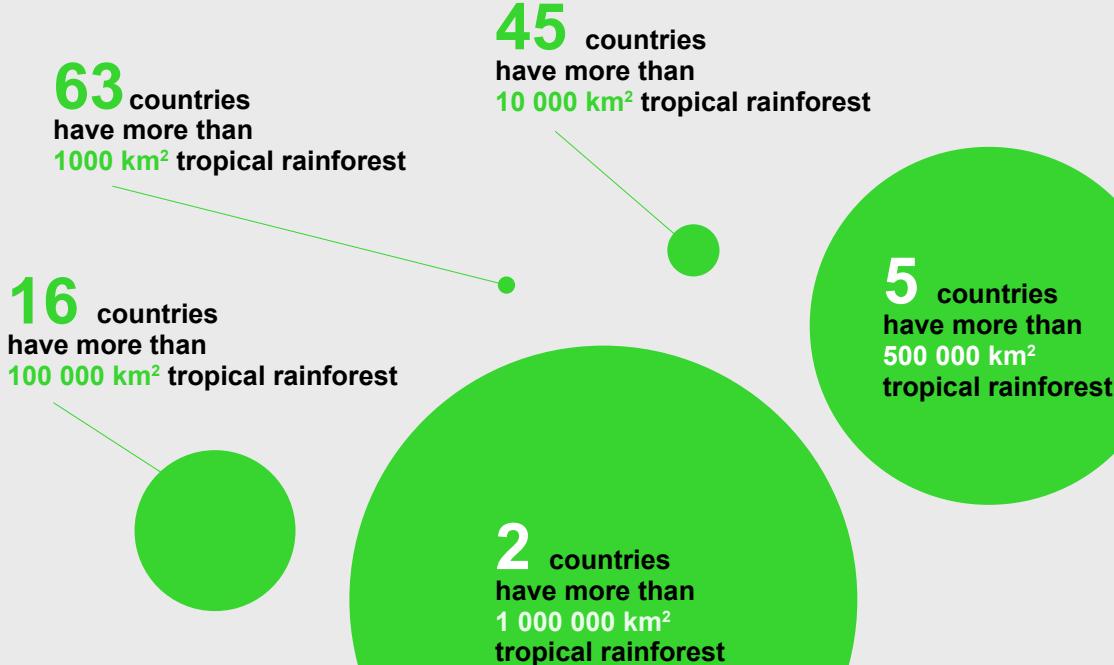

In terms of temperature, a defining factor for a tropical rainforest is that the climate is frost-free. Some areas of montane rainforest may experience rare and brief occurrences of night frost, but not more than what plants and trees that are not adapted to frost can withstand¹⁹. This wet and frost-free climate allows plants to continually grow throughout the year without periods of energy conservation due to frost or drought. This climate creates the most powerful plant growth conditions of any environment on the planet²⁰.

According to the Food and Agriculture Organization of the UN, the frost-free regions of the world are not strictly restricted to the latitude based definition of the tropical zone. There are tropical rainforests as far north as the foothills of the Himalayas, beyond the tropic of Cancer, and as far south as northern Argentina, beyond the tropic of Capricorn²¹. 

Tropical rainforest in the world: 9 538 022 km²

73 countries still have tropical rainforest

French Guyana, Guadeloupe, and New Caledonia are overseas departments of France. Taiwan is counted as a country.

Methodology

Photo: Thomas Marent

How to define a tropical rainforest?
The World Wide Fund for Nature (WWF) has defined a broad ecological region called “Tropical and Subtropical Moist Broadleaved Forests”¹³⁴. This is more inclusive than what strictly constitutes a tropical rainforest according to UN Food and Agriculture Organization (FAO) tropical rainforest definition and zoning¹³⁵. It includes drier deciduous forest types that do not have the same ecological qualities as a tropical rainforest, like the “Bahia Interior Forest”¹³⁶.

The lower lying areas of the ecozone defined by FAO as “Tropical mountain

systems” include premontane evergreen rainforests and cloud forests which grow at elevations above 1000 - 1500 meters above sea level (masl), depending on local variations. Tropical cloud forests can grow up to about 2500 masl, and they have much of the same ecological qualities as lowland rainforests¹³⁷. Although cloud forests normally receive less rainfall than lower lying rainforests, they can capture moisture directly from an almost constant mist that forms due to a cooler temperature, and this way maintain as wet and evergreen, and support a rich ever-growing

plant environment. Cloud forests normally have lower tree stature but can be more species-rich per area than the lowland rainforests.

Global Forest Watch (GFW)¹³⁸ operates with a forest definition called “primary forest”, defined as tropical humid forest that has not been completely removed and regrown in recent history (30-50 years). This forest category has been defined by scientists from the University of Maryland (Turubanova et. al.)¹³⁹, and the data is available for the public at the GFW net based forest monitoring platform¹⁴⁰. The

extent of this forest category was established for the year 2001, and it is now possible to monitor the state and change of this forest for every year from 2002 to 2019.

GFW's "primary humid tropical forest" fits quite well with FAO's "tropical rainforest" ecozone and the parts of FAO's "tropical mountain systems" ecozone that correspond to sub-montane evergreen rainforests and cloud forests¹⁴¹. It does, however, deviate from FAO in two significant areas: The Yucatan forest in Mexico, and the Chiquitano forest in Bolivia and Brazil. It also deviates from FAO in smaller parts of the South American savanna (Cerrado), southern Africa, Laos and Vietnam, and northern India. To determine if these forest areas fit the "tropical rainforest" definition of this report, we have compared them to the WWF's world's ecological regions overview¹⁴².

The Chiquitano forest in South America is clearly described by WWF as a tropical dry forest. Due to a prolonged and distinct dry season, this forest has a 500 mm yearly precipitation deficit to sustain a rainforest environment¹⁴³. The Chiquitano transitions from semi-deciduous to deciduous forest. This forest is located outside of FAO's tropical rainforest ecozone, in what FAO calls the "tropical moist forest" ecozone. While this forest falls within GFW's definition of "humid tropical forest", it does not fit well with what constitutes a tropical rainforest defined in this report, as it does go through a solid drought stress period which affects plant growth during the dry season.

On the other hand, the WWF's "Yucatan Moist Forests"¹⁴⁴ ecological region is not defined as a tropical rainforest by FAO. It lies within FAO's definition of a "tropical moist forest"¹⁴⁵, with a delimitation criteria of annual precipitation between 1000 mm and 2000 mm, and a dry season of 3-5 months. However, this is such a broad category that it includes everything from semi-evergreen broadleaved dense moist forests, which fits well with what is termed tropical rainforest in this report, to

◀◀To determine the extent and historical loss of tropical rainforest, we have used the Global Forest Watch platform and the land cover category termed "primary forest" ▶▶

more open and drier short statured woodlands like the Miombo in southern Africa¹⁴⁶ and the Cerrado¹⁴⁷ and Chaco¹⁴⁸ in South America.

Global Forest Watch's "primary forest"

To determine the extent and historical loss of tropical rainforest, we have used the Global Forest Watch platform and the land cover category termed "primary forest", which is the same as the above-mentioned definition of humid tropical forest that has not been completely removed and regrown in recent history (30-50 years). We have left out the areas of this land cover category that do not fit with a tropical rainforest definition, by comparing it to FAO's eco-zoning and WWF's descriptions of the world's ecological regions. These are the Chiquitano dry forest and parts of the dry and humid Chaco forest and Cerrado savanna in Bolivia, Brazil and Paraguay; the Kabompo Dry Evergreen Forest¹⁴⁹ in north-western Zambia and eastern Angola; and the moist deciduous forests of eastern and southern India¹⁵⁰. We have also left out most of the patches of tropical gallery (or

riparian) forests that grow in wet soils by rivers and lakes on tropical savannas. These do not have the same ecological qualities as tropical rainforests¹⁵¹, although historically they may have served as important sanctuaries for rainforest species when local climatic conditions have been unfavourable for rainforest environments.

We have used a canopy threshold of minimum 30 % as baseline for what constitutes a forest. This is a very low canopy threshold for a tropical rainforest and includes heavily degraded forest areas. It does not, however, include previously (30-50 years) deforested areas. This distinction is important, because degraded forests, if left alone, can restore key ecological functions much faster than completely removed forests (deforestation), depending on the degree of degradation¹⁵². We have compared the 30 % + canopy threshold with a 75 % + canopy threshold and found a difference of no more than 345 390 km² globally.

WWF's ecological regions of the world is a layer that can be applied to the GFW map. However, it is only possible to analyse this layer on tree cover extent with a 30 % + canopy threshold. It does not allow for analysing the extent of "primary humid tropical forest", so unfortunately the ecoregion layer cannot be applied for the purpose of this report. We have instead compared the WWF's ecoregion layer with the political boundaries of regions and municipalities, and included the primary humid tropical forest cover of the municipalities that best corresponds with the limits of the ecological regions of interest for the purpose of this report (e.g. to divide highland rainforests from lowland rainforests, and divide the dry forests of Bolivia and Paraguay from the rainforests etc.).

For some reason, the GFW platform does not include "primary humid tropical forest" data for Australia. To determine the tropical rainforest extent of Australia we have therefore compared the tree cover 30 % + layer with the Queensland tropical

rainforest layer of WWF's ecological regions, and subtracted the area of tree plantations.

For Argentina, the method applied in this report could not be used to determine the tropical rainforest cover of the country within a reasonable margin of error, so the data used here are official data from 2007. Deforestation data for tropical rainforests in Argentina is not available. However, it was possible to estimate the extent of intact tropical rainforest in Argentina using the method described in this report.

We have compared the GFW data with other research on tropical rainforest extent and degradation for each rainforest country for comparison, all of which are referenced in the footnotes. With some exemptions, there is a very high consistency between available official rainforest data and other research on rainforest cover, and the data extracted in this report for GFW's "primary forest" cover. For some countries, there are minor data discrepancies due to different forest monitoring methods. For the countries with the largest discrepancies, the differences are most likely due to the exclusion of younger secondary forest in the GFW data. At a global scale, though, the discrepancies are minor, suggesting a close match between GFW's "primary forest" category and what constitutes a natural forest within the tropical rainforest ecozone as defined in this report.

Intact tropical rainforest

We have used the Intact Forest Landscape (IFL)¹⁵³ definition to estimate how much of the world's tropical rainforest that is still left in a pristine condition. An intact forest by this definition, differs from non-degraded primary forests by having a threshold of minimum 500 km² forest patch size. This makes sense because even if the forest canopy has not been reduced, small forest patches lose their ability to uphold key ecological functions, like conserving biodiversity and store carbon. By using this definition of an intact forest, all standing tropical rainforest that do not match this is

considered degraded to a certain extent. We have estimated the extent of intact tropical rainforest by including the IFL areas that overlap the above mentioned "primary humid tropical forest" layer, excluding the areas of this category that do not fit with a tropical rainforest biome as described above.

There are different ways of defining what constitutes an intact forest, and debates are vibrant within the forest research community about the most pertinent definition. Nonetheless, intact forests are important to map and monitor so that conservation policies can urgently target the most valuable forest estates left in the world with the right measures. To halt degradation and fragmentation of intact forest areas may require different and additional policy measures than a more general policy to reduce or halt deforestation and degradation, as we have seen in many REDD+ and other initiatives the last decade. At the same time, it must be stressed that all natural forests, no matter what state of degradation they are in, do possess valuable ecosystem services worthy of conservation measures. Many degraded forests can also recover to

an intact state relatively quickly if protected, which for a deforested area can take centuries. Defining and monitoring intact forests does not underplay the ecological value of degraded forests, and measures to protect the intact forests should not undermine current or future efforts to halt deforestation in natural forest in general. But to measure and expose the real conditions of the world's last natural forests, is a crucial tool both to guide policies and to skew more conservations efforts towards forests in general.

Original tropical rainforest cover

We have used FAO's tropical rainforest ecozone¹⁵⁴ to determine the approximate original extent of tropical rainforest, and this way be able to compare the original with the present state of this magnificent forest biome¹⁵⁵. This is approximate, as no one knows exactly how much tropical rainforest there were before humans started to severely destroy this ecosystem a few hundred years ago. FAO's ecozone research constitutes an attempt to estimate both the existing and the potential extent of the world's main ecosystems by defining their present ecological zone based on primarily climatic conditions. This way, and with some caution, it is an estimation of the natural extent of the world's main ecosystems, as they were before humans began destroying them significantly. Over the course of thousands and millions of years, the tropical rainforest has to a certain extent increased and shrunk, back and forth, by natural causes like climate change. Most of the tropical rainforest destruction caused by humans, however, has happened only over the course of the past century. 

« Intact forests are important to map and monitor so that conservation policies can urgently target the most valuable forest estates left in the world. »

35) GFW primary forest 30 % + canopy cover in all municipalities in the region of Sucre except from Benítez, and in the regions of Miranda, Vargas, Caracas, Aragua, Carabobo, Yaracuy, Falcon.
<https://www.worldwildlife.org/ecoregions/nt0117>
36) GFW 2002-2019 primary forest loss subtracted
37) GFW primary forest 30 % + canopy cover in the following municipalities of Santa Cruz region: Chiquitos, Cordillera, and José Miguel de Velasco. Government forest data from the following study suggest a tropical rainforest area in Bolivia of 323 389 km² in 2013: <https://observatorioccd-bolivia.files.wordpress.com/2015/06/01-memoria-tecnica-mapa-bosque-2013-otca.pdf> The following forest areas described in this paper fit a tropical rainforest definition: Bosque Amazonico, Bosque Yungas, Bosque Tucumano, Bosque de Llano Inundables. In this figure, the Chiquitano and the Chaco dry forests as determined according to official estimates has been excluded. This is thus more accurate than what is presented in this report. Still it is not very far off, so the general picture presented in this report for the state of the tropical rainforest in Bolivia is probably within a reasonable error margin.
<http://www.fao.org/3/a-az169s.pdf> (page 9-11) the Chiquitano forest, which forms part of GFW's primary humid tropical forest definition, is not tropical rainforest.

45) Book: *National Forest Inventories: Assessment of Wood Availability and Use* redigert av Claude Vidal, Iciar A. Alberdi, Laura Hernández Mateo, John J. Redmond:
<https://books.google.no/books?id=YbGVQAAQBAJ&pg=PA124&lpg=PA124&dq=selva+misionera+argentina+extension&source=bl&ots=iD-0vUgwpls&sig=AcfU3U3Dv2L7oDe4dhTvKZNQmmB83z-FU5g&hl=no&sa=X&ved=2ahUKEwjZ8KysqKHpAhXxaYKHXuSB-cEQ6AEwGnoECAKQAQ#v=onepage&q=selva%20misionera%20argentina%20extension&f=false> (page 131) The data is from 2007, but there is very little deforestation of this type of forest in Argentina so it should be fairly accurate still. GFW primary forest includes parts of the Chaco forest that we have not been able to separate from the overall data. Argentina's tropical rainforest grows in two areas: Northern Argentina consists of the southernmost part of the Andean highland rainforest. This category includes three forest types, of which two do not fit the defition of a tropical rainforest. The category «selva pedemontana» grows up until 900 masl and receives most of its rain during 6 months or less. This is a typical monsoon forest and a transition forest between rainforest and dry Chaco forest. The forest that grows between 900 and 1600 masl is a frost free broadleaved forest that is dominated by tropical species. It is called «selva montana». Here it rains throughout the year at it's characteristics fits well with a tropical rainforest definition. This forest type has a much higher biodiversity than the two other forest types in this area. The forest that grows above 1600 masl is a subtropical clod forest and is called «bosque montano». It receives regular frost and is dominated by frost tolerant species like conifers. Argentina also has a part of the tropical rainforest that grown in the Alto Paraná ecoregion. It is known in Argentina as "Selva Misionera". Much of this region, though, is too dry or too cold to sustain a tropical rainforest. According to FAO, the forest in and around Iguazu is tropical rainforest. We have not found separate data for this forest in Argentina so we have used the forest categories in the report of "Iguazu" and "closed canopy foest". We have excluded mixed forest and open canopy forest.
<https://www.redalyc.org/pdf/540/54026849005.pdf> (page 54-55) Shows that it has not been much change in the extent of "Selva Montana" and "Bosque Montano" from 2012.

46) GFW primary forest cover 30 % + canopy cover.
Mexico uses the definition «Selva Perennifolia» which is an evergreen broadleaved forest. Under this category there is also semi-evergreen forests(subperennifolia) where as much as 25 % of the trees shed the leaves during the drier season. Mexico has more than 18 000 km² of could forest. We have not found data that separate tropical from temperate cloud forests.
<http://www.fao.org/3/a-az275s.pdf> (page 24-25)
GFW primary forest cover 30 % + canopy cover for 2010 fits very well with official data for selva perennifolia in 2010.

48) GFW primary forest cover 30 % + canopy cover.
Forest data for Panama varies greatly in different FAO-reports. To compare GFW primary forest cover with official data we have used the Forest Resource Assessment report from 2010, which has data from 2008 and is the most conservative estimate of forest cover in the country. We have subtracted the dry forest area estimate in the azuero earth project research from 2009. This indicates a tropical rainforest area of about 30 000 km². This fits well with GFW primary forest cover 2010. GFW primary forest cover also fits well with FAO's ecozone of tropical rainforest.
<http://www.fao.org/docrep/013/al595S/al595S.pdf> (page 8)
https://azueroearthproject.org/wp-content/uploads/2012/12/A.D0007_Portillo_2009_eng.pdf (page 7) <http://www.fao.org/3/a-az302s.pdf> (page 26-27) tropical rainforest in 1992 covered 42 249 km².

Mapa Forestal y de Cobertura de la Tierra de Honduras: Análisis de Cifras Nacionales, Nota Técnica N° 08, page 17 - "bosque latifoliado húmedo" = 25 787 km² in 2014.
http://www.reddccadgiz.org/documentos/doc_1697518440.pdf
In the report "Evaluacion Nacional Forestal" from 2006 page 34, official data estimate a tropical rainforest cover of 25 589 km²:
<https://books.google.no/books?id=uUq0g3J5ngC&pg=PA34&lp=g=PA34&dq=tipo+de+bosques+honduras&source=bl&ots=WcbijU5ZC&sig=ACfU3U1qJ-GgRibAm26JE7g-adHjdqT8Og&hl=no&sa=X&ved=2ahUEwiAnc6z0rPpAhVMI4sKHe08CvAQ6AEwG3oECAgQA-Q#v=onepage&q=&f=false>
In Honduras' official data to FAO and in the Forest Reference Level Honduras 2020 (page 6) - bosque latifoliado húmedo is estimated to cover more than 31 000 km² in 2019 and more than 37 000 km² in 2009. This is possibly due to a canopy cover threshold of 10 % and that it includes deforested and regrowing forest:
https://redd.unfccc.int/files/nrf_2020_honduras.pdf
<http://www.fao.org/3/a-az235s.pdf> (page 10, «bosque latifoliado»)
54) GFW primary forest cover 30 % + canopy cover in relevant regions.
55) GFW primary forest cover 30 % + canopy cover.
In "Inventario Nacional Forestal de Nicaragua 2010" page 69 it is explained that Nicaragua classifies its forests as leaved forest (bosque latifoliado), conifer forests (conífero), and mixed forests (mixto) and mangrove forests (manglar). The leaved forest consists of both rainforest and dry forest. In FREL 2019 there is a distinction between «bosque latifoliado» og «bosque seco» (dry forest). Total forest area of the former was 28 871 km² in 2015. Lots of secondary regrowing forest.

<http://www.fao.org/3/a-az191s.pdf> (page 19) «bosque maduro» and «bosque secundario» = 23 216 km² in 2013.
Just about all forest in Costa Rica grows within FAO's tropical rainforest ecoregion. There are some dry forests northwest in the country. The category «bosque maduro» represents primary rainforest. This is at least 75 years old and has to a very little degree been modified by humans. Most is located in protected areas. The area of «bosque maduro» and

- GFW primary forest cover are similar. Costa Rica also has substantial areas of secondary regrowing forests.

<http://www.joeroman.com/wordpress/wp-content/uploads/2018/02/galford-et-al-2018.pdf> - "Cuban land use and conservation, from rainforests to coral reefs" 2018 (page 3 and 8) indicate 12 668 km² of wet forest on Cuba in 2015. This deviates greatly from GFW primary forest cover and is probably due to that Cuba has lots of secondary young regrowing forest.
<https://www.worldwildlife.org/ecoregions/ht0120>
<http://documents.worldbank.org/curated/en/957541468270313045/pdf/multi-page.pdf>
64) GFW primary forest cover 30 % + canopy cover.
<http://www.fao.org/3/a-az202s.pdf> (page 11), «bosque latifoliado húmedo», «bosque latifoliado nublado», and «bosque latifoliado semi-húmedo» combined cover an area of 10 187 km² in 2012. The big deviation from GFW primary forest cover is probably due to extensive areas of secondary young regrowing forest.
http://www.grupojaragua.org.do/documents/Informe_MonitorioBicknell_BahorucoS_GJ2012-2013_ConResumen_ed.pdf
<http://tareasdominicanas.com/bosques-la-republica-dominicana/>
65) GFW primary forest cover 30 % + canopy cover.
<http://www.fao.org/3/a-az246e.pdf> (page 9) Closed broadleafed, disturbed broadleaf, mangrove, and swamp estimated area of 2 693 km² in 2010. Most of Jamaica is within FAO's tropical rainforest ecozone.
<http://www.forestry.gov.jm/node/386>
66) GFW primary forest cover 30 % + canopy cover.
<http://www.fao.org/3/a-az356e.pdf> (page 11-12) Evergreen and semi-evergreen seasonal forest, montane forest swamp forest = 1 263 km² in 2010.
67) GFW primary forest cover 30 % + canopy cover.
<http://www.fao.org/3/a-az310e.pdf> (page 13) Subtropical rainforest, subtropical moist forest, Lower mountain rainforest and mangrove forest combined area of 4 192 km² in 2008. Lots of young secondary forest. The entire island lies within FAO's tropical rainforest ecozone.
68) GFW primary forest cover 30 % + canopy cover.
<http://www.fao.org/3/a-az226f.pdf> (page 10) Forêt ombrophile = 360 km² in 2010.
69) GFW primary forest cover 30 % + canopy cover.
GFW primary forest svarer med myndigheten 2010 tall i country report fao 2015.
<http://www.fao.org/3/a-az201e.pdf> (page 12)
70) GFW primary forest cover 30 % + canopy cover.
The region Haut-Katanga in the south has about 11 km² of GFW primary forest cover. This is part of the «Miombo Woodland» and is not rainforest. Data on rainforest cover in DRC varies a lot. According to DRC's FREL from 2018 DRC had 1 145 260 km² of rainforest in 2009.
https://redd.unfccc.int/files/rdc_documenterf_soumissionfinale_29112018.pdf
https://www.observatoire-comifac.net/docs/edf2010/FR/Etat-des-forets_2010.pdf
At the same time, official data from 2005 indicate a rainforest area of 987 000 km²: <http://www.fao.org/3/a-az198f.pdf> (page 12). The large deviation may be due to that the former include secondary young regrowing forest, as the same report estimates a secondary forest area of 182 930 km² in DRC. This is forest that has been either completely removed and is in a state of regrowing or has the potential to regrow.
The Royal Society report indicate a rainforest area in DRC of 1 071 810 km² in 2005 canopy cover 70 % +:
<https://royalsocietypublishing.org/doi/pdf/10.1098/rstb.2012.0300> (page 4)
https://carpe.umd.edu/sites/default/files/focb_aprelimassess_en.pdf
71) GFW primary forest cover 30 % + canopy cover.
Total forest cover in Gabon in 2015 = 229 700 km²:
<http://www.fao.org/3/a-az217f.pdf> (page 12-13).
Royal Society report indicate a rainforest cover of 224 160 km² in 2005 canopy cover 70 % +:
<https://royalsocietypublishing.org/doi/pdf/10.1098/rstb.2012.0300> (page 4)
72) GFW primary forest cover 30 % + canopy cover.
Official data indicates 217 895 km² in 2012:
<http://www.fao.org/3/a-az189f.pdf> (page 11-12).
Royal Society report indicate a rainforest cover of 209 320 km² in 2005 canopy cover 70 % +:
<https://royalsocietypublishing.org/doi/pdf/10.1098/rstb.2012.0300> (page 4)
73) GFW primary forest cover 30 % + canopy cover.
Official data indicate a rainforest area of 191 043 km² in 2004.
<http://www.fao.org/3/a-az180f.pdf> (page 8).
Royal Society report = 200 370 km² in 2005, 70 % + canopy cover:
<https://royalsocietypublishing.org/doi/pdf/10.1098/rstb.2012.0300> (page 4)
74) GFW primary forest cover 30 % + canopy cover.
Verheggen & Defourny, 2010, rainforest cover = 69 237 km²:

https://www.observatoire-comifac.net/docs/edf2010/FR/Etat-des-forets_2010.pdf
 Royal Society report = 58 330 km² in 2005 canopy cover 70 % +:
<https://royalsocietypublishing.org/doi/pdf/10.1098/rstb.2012.0300> (page 4). Official data from 1989: <http://www.fao.org/3/a-az183.pdf> (page 11) = 32 732 km² of dense primary and secondary forest.

75) GFW primary forest cover 30 % + canopy cover.
<http://www.fao.org/3/a-az259e.pdf> (page 11 and 17)
 Total forest cover 2015 = 41 000 km². The entire country lies within FAO's tropical rainforest zone. <http://www.fao.org/forestry/country/61326/en/lbr> Some consist of areas that has 50 % of agricultural land (page 11 in the fao-report). Rainforest, both degraded and relatively intact that is not part of the forest/agricultural mosaic landscape covers an area of 34 555 km² in 2003.

Royal Society report indicates a rainforest area of 45 520 km² in 2005 canopy cover 70 % +:
<https://royalsocietypublishing.org/doi/pdf/10.1098/rstb.2012.0300> (page 4)
<https://www.worldwildlife.org/ecoregions/at0130>

76) GFW primary forest cover 30 % + canopy cover.
 Official rainforest data for the year 2010 = 46 582 km²:
<http://www.fao.org/3/a-az264f.pdf> (page 8)

77) GFW primary forest cover 30 % + canopy cover.
 Verhegghen & Defourny, 2010 indicate a rainforest area of 21 206 km² in 2010:
https://www.observatoire-comifac.net/docs/edf2010/FR/Etat-des-forets_2010.pdf (page 29)
 Royal Society report indicates a rainforest area of 21 630 km² in 2005:
<https://royalsocietypublishing.org/doi/pdf/10.1098/rstb.2012.0300> (page 4)
 FREL Equatorial Guinea 2020 indicates a rainforest area of 24 278 km² in 2018. This includes secondary forest:
https://redd.unfccc.int/files/eg_frlsubmissions_2020_01_13.pdf (page 45-46)

78) GFW primary forest cover 30 % + canopy cover in Cabinda, Zaire, Uige, Bengo, Cuanza Norte, Malanje, Luanda, Cuanza Sul, Benguela. We have not included GFW tropical primary forest that is located outside of FAO's tropical rainforest ecozone. This is in the eastern parts of the country.
 About all forest in Cabinda belongs to the Central Acrifan rainforest biome. In the rest of Angola there are rainforest areas spread out on hilltops in the north. Angola forms part of the Southern Congolian Forest-Savanna Mosaic and western congolian forest-savanna mosaic, which can sustain both savannas and rainforest. According to FAO, large parts of northern Angola lies within the tropical rainforest ecozone.

<http://blogs.wwf.org.uk/blog/habitats/forests/scientist-discovers-a-new-rain-forest-in-mozambique/>

89) GFW primary forest cover 30 % + canopy cover.
 Highland rainforest in the Imatong.
<http://www.fao.org/tempref/docrep/fao/010/ah887e/ah887e00.pdf>
<https://www.worldatlas.com/articles/ecological-regions-of-south-sudan.html>
 There are some lowland rainforest in what is called «Woodland Savannah Recently Derived from Rain Forests»: https://www.researchgate.net/publication/311390991_Ecological_Zones_of_the_Sudan
<https://news.mongabay.com/2011/06/south-sudans-tropical-forests-fast-disappearing/>

90) GFW primary forest cover 30 % + canopy cover.

91) GFW primary forest cover 30 % + canopy cover.

92) GFW primary forest cover 30 % + canopy cover.
 Togo has only 13 km² of rainforest left.
https://www.encyclopedia.com/places/africa/togo-political-geography/togo#FLORA_AND_FAUNA

93) GFW primary forest cover 30 % + canopy cover.
<https://www.britannica.com/place/Benin>

94) GFW primary forest cover 30 % + canopy cover = 50 km²
<http://www.malawi-info.net/country/article/525/malawi-forest-reserves>
<http://www.birdlife.no/internasjonalt/hyther/?id=1841>

95) GFW primary forest cover 30 % + canopy cover 2018 = 387 km². But with canopy cover at 75 % it is reduced to about 100 km². The area has a yearly precipitation of 800 to 1250 mm. WWF defines this area as «dry evergreen forest». It has two dry seasons, from August to October, and from May to July – 6 months in total. This is a mixed forest of rainforest plants, dry woodland plants and savanna plants.
<https://www.worldwildlife.org/ecoregions/at0203>
 Zambian authorities also defines this forest as «dry evergreen woodland/forest»:
http://zmb-nfms.org/iluuii/images/technical_docs/1.-CLASSIFICATION-OF-ZAMBIAN-FORESTS.pdf
http://zmb-nfms.org/iluuii/images/technical_docs/1.-CLASSIFICATION-OF-ZAMBIAN-FORESTS.pdf

104) GFW primary forest cover 30 % + canopy cover in relevant regions.

105) GFW primary forest cover 30 % + canopy cover in relevant regions.

106) GFW primary forest cover 30 % + canopy cover. We have subtracted GFW primary forest cover in the regions Odisha, Adhra Pradesh, and parts of the region Tamil Nadu that lies in the Western Ghats, which according to WWF is moist deciduous forests.

<https://www.worldwildlife.org/ecoregions/im0111>

<https://www.worldwildlife.org/ecoregions/im0150>

The following report indicates a rainforest area in India of 95 487 km² in 2015: [https://www.ncbi.nlm.nih.gov/pubmed/26615560 - Tropical Wet Evergreen and Tropical Semi-Evergreen.](https://www.ncbi.nlm.nih.gov/pubmed/26615560)

<http://www.biologydiscussion.com/forest/5-types-of-forests-found-in-india-explained/6940>

https://nrsc.gov.in/Forest_Types?q=Land_Cover_NICES

107) GFW primary forest cover 30 % + canopy cover in relevant regions.

Arunachal Pradesh lies in Asia's northern limit of frost free areas. Official data indicates a combined area of "tropical wet forest" and "tropical semi-evergreen forest" of 47 147 km² – 70 % of the total forest cover in the region in 2007: http://fsi.nic.in/sfr2009/arunachal_pradesh.pdf page 61.

Forest types in Arunachal Pradesh: http://arunachalforests.gov.in/notifications/Forest_statistics%20of%20Arunachal%20Pradesh-2017.pdf page 10

<http://fsi.nic.in/isfr19/vol2/isfr-2019-vol-ii-arunachal-pradesh.pdf>

108) GFW primary forest cover 30 % + canopy cover.

Official data of «evergreen forest» = 26 056 km² in 2015. «Mixed deciduous forest» og «coniferous forests» combined cover 94 000 km², of which most id «mixed deciduous forest»:

https://redd.unfccc.int/files/lao_2018_frel_submission_modified.pdf page 5.
http://www.rfo-sea.org/national_summary.htm

<http://www.fao.org/forestry/country/61326/en/lao/>

«Mixed deciduous forest» is a forest type that consists of semi-evergreen moist forests and conifer forests. It is likely that GFW primary forest cover for Laos includes the parts of the forest type that is more similar to «tropical semi-evergreen moist forest». GFW primary forest cover does not

overlap with WWF's ecozone called «central indochina dry forest», which is the only forest zone of the country that do not sustain rainforest in any way. There are five other eco regions in the country that do sustain a rainforest environment:

<https://www.worldwildlife.org/ecoregions/im0137>

<https://www.worldwildlife.org/ecoregions/im0121>

<https://www.worldwildlife.org/ecoregions/im0136>

<https://www.worldwildlife.org/ecoregions/im0152>

<https://www.worldwildlife.org/ecoregions/im0210>

http://portal.gms-eoc.org/uploads/map/archives/map/GMS-Ecoregions_18_hi-res_10.jpg

https://books.google.no/books?id=PQ8NHpLPb70C&pg=PT257&lp-g=PT257&lq=mixed+deciduous+forests+laos&source=bl&ots=GAaNAUKBw4&sig=ACfU3U2EwECTzfJqtIFW_2kZjdcvieKcw-g&hl=no&sa=X&ved=2ahUKEwj2u8e4ntHpAhXG0qYKHQ8kBu0Q6A-EwEHoECAoQAOQ#v=onepage&q=mixed%20deciduous%20forests%20laos&f=false (chapter 3.3).

<http://www.mekonginfo.org/assets/midocs/0001714-environment-forests-and-trees-of-the-central-highlands-of-xieng-khouang-lao-p-d-r-a-field-guide.pdf>

109) GFW primary forest cover 30 % + canopy cover.

<https://www.worldwildlife.org/ecoregions/im0137>

National Forest Inventory and Statistics (NFIS) indicates a total evergreen forest cover, including mangroves, of 72 240 km² in 2016, and a secondary forest cover of 41 050 km²: http://www.rfo-sea.org/national_summary.htm. The FREL 2016 indicates an area of 77 320 km² for the same forest type in 2010.

https://redd.unfccc.int/files/vietnam_frl_modified_submission_final_for_posting.pdf

<http://www.mekonginfo.org/assets/midocs/0002503-environment-forest-resources-management-and-development-in-vietnam.pdf> page 1, Department for Forestry Development Closed broad-leaved tropical evergreen and semi-deciduous 56 486 km².

110) GFW primary forest cover 30 % + canopy cover.

Includes parts of "Southeastern Indochina Dry Evergreen Forests":

<https://www.worldwildlife.org/ecoregions/im0210>. Annual precipitation varies from 1200 mm to 2000 mm and with a dry season of 3-6 months. This is semi-evergreen forest and parts of it can be defined as tropical rainforest. GFW primary forest cover fits well with FAO's delimitation of the tropical rainforest ecozone.

Official data indicates a tropical evergreen forest cover of 52 198 km² in 1998:

<http://www.fao.org/3/ac648e0a.htm>

<http://portal.gms-eoc.org/maps?cmbIndicatorMapType=archive&cmbIndicatorTheme=35&cmbIndicatorMap=10>

<https://wildlifethailand.com/blog-posts/plants-and-fungi/96-forest-types-in-thailand>

<http://forprod.forest.go.th/forprod/ebook/%E0%B8%81%E0%B8%B2%E0%B8%A3%E0%B8%9B%E0%B9%88%E0%B8%B2%E0%B9%84%E0%B8%A1%E0%B9%89%E0%B9%83%E0%B8%99%E0%B8%9B%E0%B9%A3%E0%B8%90%E0%B9%80%E0%B8%97%E0%B8%9E%0B9%84%E0%B8%97%E0%B8%A2%20thailand%20eng.pdf>

111) GFW primary forest cover 30 % + canopy cover.

Country report 2015 til FAO, Closed Forest Broadleaved and mangroves (40 % + canopy cover) = 22 010 km² in 2010, Open Broadleaved Forest = 43 110 km².

<http://www.fao.org/3/a-az306e.pdf> (page 21)

<https://www.worldatlas.com/articles/ecological-regions-of-the-philippines.html>

https://www.senate.gov/publications/SEPO/AAG%20on%20Philippine%20Forest_Final.pdf

FAO's tropical rainforest ecoregion and GFW primary forest cover are similar.

112) GFW primary forest cover 30 % + canopy cover.

Includes parts of the eco region Southeastern Indochina Dry Evergreen Forests:

<https://www.worldwildlife.org/ecoregions/im0210>. Annual precipitation varies from 1200 mm to 2000 mm and with a dry season of 3-6 months. This is semi-evergreen forest and parts of it can be defined as tropical rainforest.

Official data of semi-evergreen, evergreen and mangrove forests to cover 41 050 km² in 2014:

http://www.rfo-sea.org/national_summary.htm

116) GFW primary forest cover 30 % + canopy cover.
<http://www.fao.org/3/a-az341e.pdf> (page 8) «montane forest», «sub-montane», «lowland rainforest», wet monsoon forest» and «mangrove forest» cover 3 145 km² in 2010. «wet monsoon» has up to 3 months of dry season. It borders the rainforest and the two forest types to not differ much. They have many of the same species. Sri Lanka also has over 11 000 km² of «dry monsoon forest». This receives up to 2000 mm of rain annually, and has a dry season of 3-6 months. Parts of this forest does also fit with a tropical rainforest definition.
http://lk.chm-cbd.net/?page_id=182
<http://www.fao.org/3/a-az341e.pdf>

117) GFW primary forest cover 30 % + canopy cover.
<http://www.fao.org/3/a-az174e.pdf> (page 15) total forest cover 2015 = 3 770 km².

118) GFW primary forest cover 30 % + canopy cover in Pingtung and Taitung. The tropical zone in Taiwan is far south in the country. This is a tropical monsoon forest type similar to the one in southern China.

Official rainforest data for the state of Queensland in the year 2018 is 19 810 km². Subtropical rainforest in the southern parts of the state.

https://www.agriculture.gov.au/sites/default/files/abares/forestsaustralia/documents/sofr_2018/web%20accessible%20pdfs/SOFR_2018_web.pdf (page 52)

GFW primary forest cover 30 % + 2018 indicates only 127 km². This cannot be correct, as the World Heritage Site «Wet tropics of Queensland» has an area of 8 944 km² of mostly tropical rainforest, and Daintree National Park has protected a continuous rainforest of 1 200 km² since 1988. In addition, this does not fit well with the fact that GFW estimate an intact rainforest area of 4 152 km² within Australia's tropical belt.

<http://www.environment.gov.au/heritage/places/world-wet-tropics>

125) GFW primary forest cover 30 % + canopy.

<http://www.fao.org/3/a-az212e.pdf> (page 13)

<https://www.worldwildlife.org/ecoregions/oc0105>

<http://www.fao.org/docrep/006/AD672E/ad672e08.htm>

126) GFW primary forest cover for the year 2000 estimates 0 km². This does not seem to be correct.

IUCN estimate in the report Climate Change and Biodiversity in the European Union Overseas Entities that tropical rainforest cover 21 % of New Caledonia's land mass in 2008. This equals 3 900 km². We have added the mangrove forest area from 2009 Country Report to FAO 2015. <https://portals.iucn.org/library/sites/library/files/documents/2010-064.pdf>

<http://www.fao.org/3/a-az289f.pdf> (Page 8) «Forêt dense sur substrat volcanico-sédimentaire» and mangroves covered 6 826 km² in 2009. https://www.researchgate.net/publication/280975121_New_Caledonia_A_Pleistocene_refugium_for_rain_forest_lineages_of_relict_angiosperms

127) GFW primary forest cover 30 % + canopy cover.

<http://www.fao.org/3/a-az371e.pdf> (page 7-10) "mid-height forest", "low forest", "swamp forest", "mangrove forest" cover a combined area of 4 445 km² in 1992.

<https://www.worldwildlife.org/ecoregions/aa0126>

128) GFW primary forest cover 30 % + canopy cover.

http://micronesica.org/sites/default/files/2_kitalong.pdf

<http://palaeoecosystem.weebly.com/tropical-rainforest.html>

<http://www.fao.org/3/a-az301e.pdf>

129) GFW primary forest cover does not exist on Samoa. This is probably due to the fact that almost all is secondary young forest, heavily degraded and open secondary forest.

<http://www.fao.org/3/a-am246e.pdf> page 10, «medium forest» (between 40 og 65 % canopy cover) was estimated to cover 726 km² in 2004.

Closed forest (over 65 % canopy cover) covered only 0,8 km².

<http://www.fao.org/3/a-az325e.pdf>

<https://www.worldwildlife.org/ecoregions/oc0112>

130) We have used GFW to find «Intact Forest Landscapes» in rainforest regions with canopy cover at 75 % +.

131) The IFL area of Himachal Pradesh has been subtracted from the total, as there is no primary humid tropical forest there.

132) We have included the municipalities of the region Santa Cruz that best correspond to the Chiquitano and Chaco forests, which are Chiquitos, Cordillera, and José Miguel de Velasco. This is approximate. In the municipalities that are covered with Chiquitano and Chaco forests the deforestation was at almost 9 000 km² in the period.

133) In the municipalities that are covered with Chiquitano and Chaco forests the deforestation was 1212 km² in the period.

Rainforest Foundation Norway supports indigenous peoples and traditional populations of the world's rainforests in their efforts to protect their environment and secure their customary rights. RFN was established in 1989 and works with local environmental, indigenous and human rights organisations in the main rainforest countries in the Amazon region, Central Africa, Southeast Asia, and Oceania. RFN is an independent organisation, and part of the international Rainforest Foundation network, with sister organisations in the United Kingdom and the USA.

Rainforest Foundation Norway, Mariboes gate 8, 0183 Oslo Norway
